Your Brain on Water

Being in, on, around, or under the water has many mental health benefits

by Elaine N. Howley

You can get that feeling, like you were just made for water and it's your happy place? You're certainly not alone.

"There's a neurochemical that comes with long exposure to water, and it's oxytocin and ancient and timeless," says Matthew L. Morales, a long-distance open water swimmer and water rights activist in Boulder, Colorado, who released a book-length love letter to water titled "Words on Water: Droplets of Wisdom from Rivers, Lakes, and Oceans" in March 25, UK World Water Day.

"What I've been in the water for two or five hours, I tend to have my mind in a different place and it brings a certain clarity of what's important to me right now and what's not. I love that [on feeling] about being in the water for a long time.

"I think a lot of people can get that sensation in short distances or even floating in the ocean by the beach. But for me, it's this very deep kind of transcendence, like I'm stepping out of myself and into my aqua self and I belong here. This is kind of my home, and that's why I love it so much. I want to protect it."

If you found yourself nodding in agreement while reading any part of the thoughts, you're not a marooned sea-lion yearning for the mainland. You're likely one of the many millions of Masters swimmers who've experienced the sensation that being in water is good for your mental health.

The quest to answer that big question became the life work of Wallace J. Nichols, a marine biologist who penned the blockbuster 2014 book "Blue Mind: The Surprising Science That Makes Living Near, In, On, or Under Water Can Make You Happier, Healthier, More Connected, and Better at What You Do."

Nichols passed away in 2020, but his work lives on through the Blue Mind Movement and a network of researchers, psychologists, neuroscientists, and authors all corresponding the world that we really are better in, on, or by the water. Their work aims to describe the exact mechanisms of that connection and provide the scientific evidence that will persuade everyone that our oceans, rivers, lakes, seas, pools, and other waterways are worthy of preservation.

Keeping swimmers' hair healthy and chlorine free.

There's plenty of science to help make that argument. Those good feelings are rooted in basic brain chemistry and biology.

First, when you enter water—which is typically cooler than your body temperature—you're triggering the mammalian dive reflex, an ancient response that we share with whales, seals, and other marine mammals, says Catherine Franssen, a neuroscientist, consultant, and assistant professor in the School of Life Sciences and Sustainability at Virginia Commonwealth University.

The dive reflex is designed to help you hold your breath underwater and it lowers your heart rate to slow oxygen consumption.

Immersion in cool water also activates the parasympathetic nervous system, which helps soothe you from head to toe. Whereas stress triggers the sympathetic nervous system, which is often referred to as the fight-or-flight response, by focusing your attention on breathing and moving your body in the water—or even back when threatened, the parasympathetic nervous system works in opposition by slowing your heart rate, reducing blood pressure, and enhancing digestion and metabolic processes. Because of these responses, it's often referred to as the rest-and-digest system.

Meanwhile, your brain is working overtime on another arm at aquatic world, Franssen says, as it deals with physical activity and immersion in water. These powerful chemicals provide an incredible, pleasure, mood stabilization, stress management, and analgesic and even pain relief, Franssen says.

"That pain relief extends both physically and emotionally, so that calm, happy, clear feeling you get after swimming, it's not just a metaphor. It's actually biological."

This all begins on first immersion, but once you start actually swimming, you engage muscles, tendons, and bones to move you forward. Alongside the internal chemical stirfry, that physical activity can create a state of "effortful calm," Franssen says.

It's powerful stuff too because while swimming, you can undergo anxiety in ways that can be difficult to do on land. Swimming "occupies the body just enough to stop the rumination without overstimulating your mind," she says.

Because of that combination, so often get fewer intrusive thoughts while swimming and that creates a sense of being in a time after our swim is over. Especially on long swims in open water, "you've got this rhythmicity of movement and stability of weather and there's this low, consistent level of sensory input," Franssen says. This allows you to "cognitively relax. You don't have to constantly deal with brand new things. You go into a flow state and just exist in that space."

This is why many of us get our best, most creative ideas and solutions to problems while we're in the water. It's a perfect mixture of relaxation and reduction of external stimuli. It's a sense of opportunity for the subconscious mind to speak up and be heard above the din of the everyday.

Moving meditation is another term many people use to describe the calm, peaceful space their brain seems to enter when they're swimming. And this is where neuroscience meets psychology. Matthew White, a health and environmental psychologist at the University of Exeter in Austria, describes that feeling of flow as leaving one's "acute mindfulness."

Swimming seems particularly well-suited to helping us get to that state of presence in the moment in part because it hones brain regulation. Indeed, any meditation practice starts with controlling your breath. In addition, the removal of other stimulus gives you to tune in to what's going on with your body and your breath as you let the world go and focus on moving forward through the water.

So it's clear that we're wired to love being immersed, but why exactly that's the case isn't fully understood, even by those who've been studying this connection at length.

"I've been doing this for 15 years, and I'm afraid I've got more questions than answers," White says. "Every time we look at one thing, a new question comes up."

An avid outdoor swimmer and surfer, White grew up on the coast of the Isle of Wight and says he has always been fascinated by his own and other people's attraction to the water.

Eventually he teamed up with a doctor studying chemical pollution and destruction of the marine environment who was frustrated that the alarm-sounding approach wasn't catalyzing the attention it deserved.

The pair determined that enhancing the connection to nature these environments provide humane benefits that would be irresistably real if they were destroyed might be a better way to gain traction for conservation efforts.

So they got to work, digging in to why people love the water and how best to motivate the public to take care of it. In time, that research led White to develop three broad ways of explaining our connection to the water: evolutionary, cultural, and individual factors.

"Pain relief extends both physically and emotionally, so that calm, happy, clear feeling you get after swimming, it's not just a metaphor. It's actually biological."

Catherine Franssen, assistant professor in the School of Life Sciences and Sustainability at Virginia Commonwealth University

Evolutionary

White says he's cautious about this aspect because he doesn't want to get ahead of the science. But he concedes: "I don't think we can deny it's cruelty—we need fresh water to live. But it's also important attractor in terms of a biological sense."

What's more, he says, "there's relatively good evidence that we're well-adapted as a species to spending time in water." He points to the commonsense "habitat" theory of humans, which, among other things, posits that humans evolved along the coastal margins of Africa and more relative ease of navigation for how we came to rely on and love the water so much.

We know that species evolve quickly in response to new or changed selective pressures, White says. Weeks-bumps have where fossils of early hominids have been unearthed suggest that water was a major component of their diet.

Agriculture, of course, which is rich in omega-3 fatty acids, lean proteins, and other nutrients that can support the growth of a big brain and complex cognitive functions, is also closely connected to the water evolutionary, cultural, and individual factors.

Cultural

Culturally, humans have long been associated with the water, but even so, water can be a dangerous place. In some parts of the world, fear of accidental drowning prevented generations of people from accessing open water. But by the mid-19th century, swimming was becoming a popular pastime, most notably in Paris, and parts of Western Europe.

This is in part because of a 1703 book by Richard Russell, "A Dissertation Concerning the Use of Sea Water in Diseases of the Glands, etc." Russell was "a doctor who argued that bathing in sea water could cure a whole host of diseases based on case studies," White says. The British royal family took note of the good doctor's findings and set up 12 bathing-water hospitals around the coast of England.

"Similar things were happening in France, and during this time, there came an idea that this is a medical therapy with royal approval, which then attracted the rich people," White says.

In time, that rediscovered enthusiasm for getting into the water trickled down to poorer people, and as a result, seaside bathing sites and resorts developed that encouraged rest and relaxation by the sea.

The coinciding industrial revolution, which eventually led to the development of more leisure time for the working class as well as the development of rail travel, helped create the sheer of the seaside summer holiday.

INFINITY

Individual

These cultural and evolutionary forces can apply pressure, but ultimately, the choice to engage with water is an individual one, and that's where the third factor comes into play, White says.

For those who enjoy the water, often there's a personal history of pleasurable time by the sea in a safe context. White's research suggests that many people's first and most memorable places that are positive because they're associated with family, care, and quality time and attention from parents.

Franssen also cites the power of individual affinity in our relationship to water and says memory plays a role. For many of us, spending time at the beach or in or on the water connected with happy protected times with our families, and childhood bath time typically featured the close attention of a parent or caregiver. That positive association intensifies when you consider cues that your brain connects with each time you visit the water.

Perhaps those two pieces together—the rhythmic exercise component with the emotional safety and positive feelings we have from childhood—are the ingredients that make swimming in it's very easy for our brain to want to do that," Franssen says.

What's more, those brain memories also tend to return to the places we vacationed as children, White says, and this makes swimming in those places create stability, harmony, and safety in a world going to spend money on a meaning holiday, you're likely to go to the place that you associate with positive feelings and memories.

Not everyone loves the water, however. Memory can cut both ways, and a traumatic experience in the water can work someone's connection to it for life. Plus, context matters. "If you're trapped at sea in a small dinghy 50 miles out of land, that's not such a calming experience, right?" White says.

INFINITY

Rather, there's a happy medium. When he's asked whether chlorine pools can be as beneficial as open water, he says, "Humans also have an innate connection to rain before. White was it's a rich ecosystem." To think the answer is that is really clear—it's the margins." It's the transitional, littoral space between open sea and shallow forest where many of us will feel a particularly strong connection to the natural world around us.

This shared provides access to the safety of land but also the bounty of the sea.

"Historically as a species, we spent most of our time in the shallows," White says. "We're talking 10 to 20 metres either way [into the water or up on land] that seems to be the sweet spot. It's being close to the land but also in water that we can be the magic spot," White says.

It's certainly not a coincidence that the blue mind lifestyle doesn't work for everyone. Indeed, someone who's had a negative experience in or around water is also not to be wary of aquatic spaces.

And he adds that open water can be more anxiety-inducing than the average pool. "But if you can ease that anxiety, that's resilience-building and that can actually be good in the long run," Facing one's fears is a classic way to cope.

In speaking to Masters swimmers—most of whom get great enjoyment from being in the water and clearly already embrace the blue mind lifestyle—White says he's pleased to see that more people are starting to pay attention to the ocean.

His research is designed to help people grasp "that don't understand the potential benefits" that water can provide and then make concerted efforts to preserve these spaces. Some of his research has been picked up by the European Environment Agency, which provides objective, reliable, evidence-based info on the environment and climate to EU member states.

"I'm really happy to see that the science is getting more compelling. This work matters because it costs money to have a water clean," he says. "But when we do a cost-benefit analysis, you're getting a 10 to 1 or 100 to 1 return on investment."
